

# How to detect when an optical module is inserted into a network card

## Overview

Execute the following command to view detailed interface and optical module status: `ethtool <devname>` The output includes interface rate, module rate, link status (Link detected: yes is required for normal module operation), and interface configuration details. This guide introduces how to read optical module information when it is installed on a network card in a Linux system. It takes the device name (like `swp1`) as an argument. See `man ethtool(8)` for details. If. This guide gives a practical, CLI-focused workflow for checking SFP health and diagnostics on Cisco switches, shows the exact commands you'll use, explains what the numbers mean, and compares OEM (Cisco) vs third-party modules so you can pick the right SFP module supplier for reliability and cost. Because SFP modules act as the physical interface between networking equipment and transmission media, verifying that a module is installed correctly and operating within its optical parameters is essential for maintaining stable network connectivity.
