

# Neutral wire of high-voltage distribution box

## Overview

A neutral wire allows the three phase system to use a higher voltage while still supporting lower voltage single phase appliances. In high voltage distribution situations it is common not to have a neutral wire as the loads can simply be connected between phases (phase-phase). The connecting wires in water tight electrical box should be insulated and the joints should not be loose. There should be no exposed live parts in waterproof cable box. The neutral wire in plastic weatherproof electrical box should be connected through the terminal board and separated from the. If the Neutral Conductor is opened, broke or lost at either of its source side (distribution transformer, generator) or at load side (distribution panel of a consumer), the distribution system's neutral conductor will “float” or lose its reference ground Point. It provides a reference point for voltage levels and carries the return current from the load back to the power source.
