

Where is the relay protection for the transformer substation located

Overview

In distribution substations, the bus protection is often provided by overcurrent relays, phase and neutral, located on either the low-voltage or high-voltage side of the transformer. Fuse protection has the merits of being economical and requiring little maintenance. Fuses require no circuit-interrupting devices. ABB's transformer protection relays are used for protection, control, measurement and supervision of power transformers, unit and step-up transformers, including power generator-transformer blocks in utility and industry power distribution networks. Effective relay protection depends on. Generator protection covers: phase-to-phase short circuits in stator windings, stator ground faults, inter-turn short circuits in stator windings, external short circuits, symmetrical overload, stator overvoltage, single- and double-point grounding in the excitation circuit, and loss of excitation. All equipment installed in a power electrical system have standardized ratings for short-time withstand current and short duration power frequency.
