

Why do optical cables have electrical current

Overview

The light from fiber optic cables is converted into electric current using a photodiode at the receiving end. Here's a breakdown of how this conversion happens: Fiber Optic Transmission: Data is transmitted as pulses of light through thin strands of glass or plastic called fiber. A TOSLINK optical fiber cable with a clear jacket. These cables are used mainly for digital audio connections between devices. A fiber-optic cable, also known as an optical-fiber cable, is an assembly similar to an electrical cable but containing one or more optical fibers that are used to carry. An optic cable, or fiber optic cable, is a thin strand of glass or plastic that transmits data as pulses of light instead of electrical signals. Each strand is roughly the width of a human hair, yet a single fiber can carry hundreds of gigabits of data per second over distances that would cripple a. These strands, known as fibre optic cables, have revolutionised telecommunications because they transmit information using pulses of light. Light signals: Unlike electrical messages sent through copper wires, light signals from one fiber inside a fiber cable do not interfere with one another.
