

Will a 100-meter-long pigtail affect transmission

Overview

While industry standards claim a generic “100-meter rule,” the physics of copper transmission is far less forgiving. This guide strips away marketing. If an Ethernet cable exceeds its maximum recommended length of 100 meters (328 feet), the data signal weakens, a phenomenon known as attenuation. This leads to a cascade of network problems, including significantly slower connection speeds, data packet loss, increased latency (lag), and eventually. Ethernet cables are a crucial component in ensuring smooth data transmission across networks. Understanding the relationship between cable length, signal loss, and overall network performance is essential. Local area networks (LANs) have historically been designed in a way that ensures all end devices are within 100 meters (m) of a telecommunications room (TRs) to comply with industry cabling standards. Now with the adoption of smart building technologies, more devices than ever are being connected. This reduction of signal happens along any length of cable for any type of transmission—and the longer the length, the greater the loss. Based on these performance parameters, industry standards standardized on the 100-m distance and have stuck with it even as new applications with higher. Power over Ethernet (PoE) provides a convenient and cost-effective approach to achieve both power and data connectivity on a single connection. Thus, PoE extension is ultra important to achieve long-range.
